

## 2015 Texas Panhandle Sorghum Silage Trial

*Jourdan Bell, Ted McCollum, Dennis Pietsch, Ronnie Schnell,  
Preston Sirmon, and Daniel Tyrer*

### **Introduction**

The 2015 Texas A&M AgriLife Research and Extension Forage Sorghum Silage Trial at Bushland consisted of 100 entries of which 49 were non-BMR (brown midrib) and 51 were BMR forage sorghum and sorghum-sudangrass hybrids. Of the 100 entries, there were 14 photoperiod-sensitive hybrids of which ten were non-BMR and four were BMR hybrids, and there were 5 brachytic entries. All entries were evaluated for yield and nutritional components. Select entries were evaluated for grain yield upon seed company request. Due to sugarcane aphid pressure, all entries were rated for sugarcane aphid damage.

### **Materials and Methods**

The trial was funded by commercial company entry fees. Evaluated hybrids were entered at the discretion of the seed companies. Entries were planted in a randomized complete block design. Photoperiod sensitive (PS) entries were blocked separately in each rep. Irrigation was applied with a center-pivot sprinkler with mid-elevation nozzles on 60-inch spacings and scheduled by the cooperator based on crop water demand.

### **Cultural Practices:**

Trial Location: 1 mile northeast of Bushland (35.203616, -102.030475)

Cooperator: Michael Menke

Previous Crop: Fallow

Soil Type: Pullman clay loam, pH 7.5

Planting Date: June 24, 2015

Planting Rate: 100,000 seeds/acre

Herbicides: Atrazine (1.5 lbs a.i./ac) + glyphosate (16 oz/ac) prior to planting

Fertilizer: Manure 2014 followed by 100 lbs N/ac in 2015

In-season Irrigation: 5.5 inches

In-season precipitation: 17.2 in.

Plot Size: Four, 30 inch rows by 25 ft.

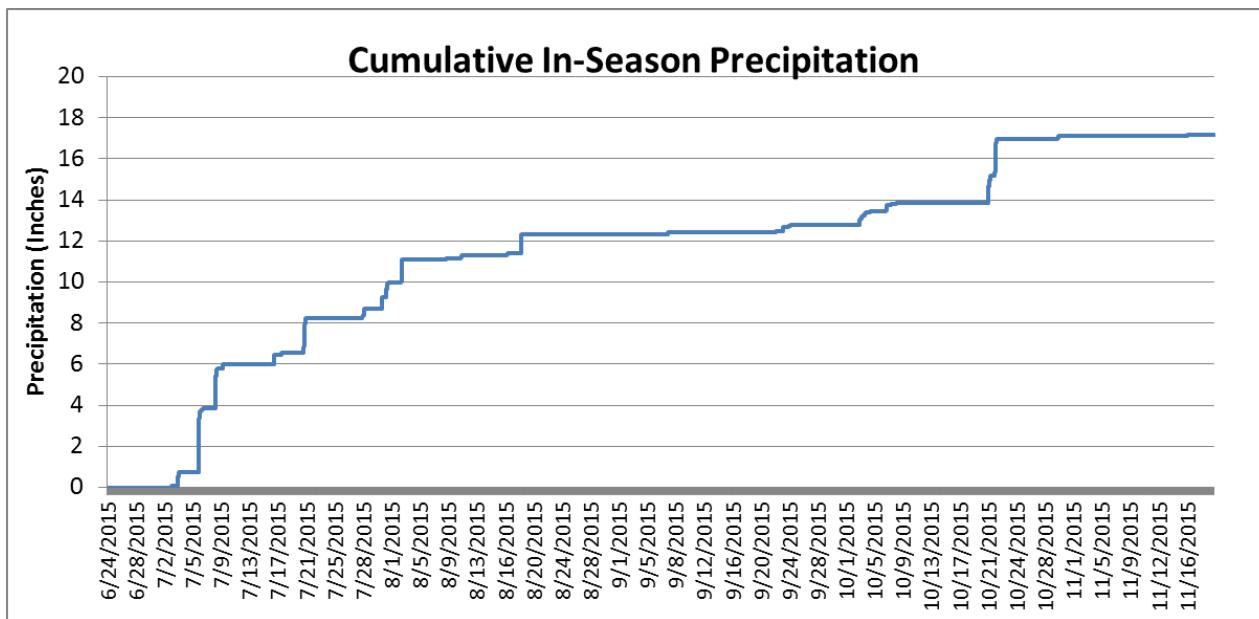

Replications: 3

Study Design: Randomized Complete Block

## Nutrient Analysis Included:

### Forage Analyses defined:

- CP: Crude Protein
- TDN: Total Digestible Nutrients (by Weiss equation) an index of energy concentration.
- NDF: Neutral Detergent Fiber; cell wall fraction of the forage
- ADF: Acid Detergent Fiber; a fraction of the cell wall includes cellulose and lignin, which is inversely related to energy availability
- IVTD: In Vitro True Digestibility; estimate of forage disappearance in the digestive tract
- NDFD: NDF digestibility; estimated fiber digestibility
- RFQ: Relative Forage Quality - an index for comparing forages, not just alfalfa. RFQ is based on the same scoring system as RFV with an average score of 100; higher scores indicate better feeding value.
- Milk/ton: An index based on several variables that influence intake and nutritive value. These are applied to a standard dairy cow to project milk produced per ton of forage.

**Figure 1.** Cumulative in-season precipitation.

Harvest of the different hybrids did not occur on a single date. Grain producing hybrids were harvested for forage yield when grain reached soft dough. Hybrids that had not reached soft-dough were all harvested on the last sampling date (November 20, 2015). This included the photoperiod sensitive hybrids and some late maturing hybrids. Forage yield was determined by harvesting all plants from 25 ft<sup>2</sup> area (1 row by 10 ft.) within each plot. If possible, plants were harvested from a non-lodged portion of the plot to preserve forage quality. Lodging and plant height were recorded at harvest. A portion of the chopped forage was dried at 140°F to

determine harvest moisture. The remaining portion of the chopped forage from each plot were then composited by entry and submitted to Dairy One Lab, Ithaca, NY for forage analyses. Forage constituents are reported on a dry matter (DM) basis.

Statistical analyses were completed using SAS 9.4. Adjusted least significant differences for multiple comparisons were determined using Tukey's HSD. Effects and comparisons were determined significant at the 0.05 probability level.

Average trial yield was 22.8 tons/acre (Standard Dev 2.53; CV 11%) across all hybrids with the average yields of photosensitive, non-BMR hybrids being greatest (Table 1). Yields ranged from 36.7 to 15.5 tons/acre for the individual hybrids (Table 2); however, when evaluating the performance of the top yielding hybrids there were no statistical differences between the top 20 hybrids with yields ranging from 29.1 to 36.6 tons/ac at the 0.05 probability level (Table 5). Table 5 lists the top 25 yielding hybrids. High in-season precipitation and optimal temperatures in addition to supplemental precipitation contributed to optimal yields. Although the average yield differences between sorghum types are numerically different, evaluation of the individual hybrids reveal an overlap between different hybrids and types as reflected in the non-statistical differences. If possible, producers should evaluate hybrids based on several years of production data from multiple trial locations to capture differences in the growing season conditions.

The risk for lodging is an important consideration in forage sorghum selection. While genetics does affect a hybrids lodging potential, lodging is strongly influenced by crop management including population, fertility, crop water (soil moisture + precipitation + irrigation), and harvest timing. Increased populations can potentially maximize production under optimum conditions, but at higher populations, the stalk diameter decreases making the plant more susceptible to lodging. To evaluate the influence of population on lodging and production, three hybrids (Silo 700D BMR, NK300 and AF7202) were planted at a population of 75,000 seeds/acre for comparison to the trial population of 100,000 seeds/acre. There was a trend for the 100,000 seed/ac population to yield greater for Silo 700D BMR and AF7202, but there were no significant differences in yields between populations for the evaluated hybrids (Table 10). However, lodging was lower at 75,000 seeds/acre for the three evaluated hybrids. Population did not affect the days to half-bloom (HB). In addition to agronomic management, it is often perceived that BMR forages are more susceptible to lodging. In this trial, lodging appeared to be a function of individual hybrid, photoperiod response, and potentially population not BMR forage type. Currently, the industry recommended planting population is 75 – 80,000 seeds/acre. Because there were no significant differences in forage yield between the two evaluated populations in 2015, the 2016 trial will be planted at 80,000 to minimize lodging.

Days to HB were recorded for all hybrids based on weekly observations. The average days to HB were 77 with the minimum number of days being 63; several PS hybrids did not reach HB

during the evaluation period. Grain yield was obtained in November once requested hybrids had reached physiological maturity. Heads were harvested from a 25 sq. foot area (1 row x 10 feet), and processed using a belt thresher. Grain yields will be available in an addendum to this report.

Five brachytic dwarf forages were part of the 2015 entries (AF7102, AF7202, AF7401, SP 3903BD, and Sweet Bee BMR) (Table 7). Brachytic dwarf hybrids are marketed as shorter stature hybrids that yield relative to taller hybrids due to a shortened internode. It is also advertised that they have greater standability due to their shorter stature. The brachytics were considerably shorter than the trial average (79.1 inches vs. 98.1 inches). The average lodging for the brachytic hybrids was lower than the trial average (20% for brachytics vs 29% for trial average), but the lodging varied greatly by brachytic hybrid (0 to 62%). While the average brachytic yield (20.7 tons/ac; Stdev=3.6 tons/ac) was slightly less than the trial average (22.8 tons/ac; Stdev=4.2 tons/ac), this was not statistically different. Similarly, there was a trend for nutritional characteristics to be greater for the brachytic forages (Table 8).

Forage characteristics contributing to nutritive and feeding values are shown in Tables 1-6. From the broad averages for different forage types shown in Table 1, the photoperiod sensitive types appeared to contain greater ADF and NDF, while the BMR types on average contained lower digestible fractions. The BMR trait reduces lignin concentration in forage and, on average; lignin concentration was lower in BMRs than non-BMRs. BMR-PS forages had only slightly lower lignin values than the non-BMR PS forages (Table 1). Lignin reduces fiber digestibility and energy density of forage. Note that fiber digestibility (NDFD48; Table 1) reflected the differences in lignin concentration and was also reflected in the milk/ton indices. Average starch content was lower for the PS hybrids because they do not produce grain.

The discussion above addresses **broad averages** for types of forage sorghums, grain sorghums evaluated as silage, and sorghum/sudangrass hybrids evaluated in the 2015 test. We recommended individual hybrids not be selected or disregarded based on the sorghum type nor based on the relative comparison among types. There is overlap among hybrids in these type categories. Evaluate the data based on the individual hybrid, not the type category.

Sugarcane aphids were found in the plots on August 21, 2015. The entire field was sprayed aerially with Transform on August 26 at 1.5 oz/ac at 3.0 GPA. Sugarcane aphid ratings were obtained on August 30, September 10 and October 28 (Table 9). Ratings ranged from 0 to 80% (0 to 8) infested, damaged leaf area based on a rating scale developed by Texas A&M AgriLife Entomologists Pat Porter, Ed Bynum and Blayne Reed.

**Texas A&M AgriLife Sugarcane Aphid Rating Scale:**

- 0: no aphids or honey dew found
- 1: 10% of leaf area infested or damaged or colonies establishing on lower leaves or some honey dew visible on 2 or less leaves
- 2: 11-20% of leaf area infested or damaged
- 3: 21-30% of leaf area infested, damaged or dead
- 4: 31-40% of leaf area infested, damaged or dead
- 5: 41-50% of leaf area infested, damaged or dead
- 6: 51-60% of leaf area infested, damaged or dead
- 7: 61-70% of leaf area infested, damaged or dead
- 8: 71-80% of leaf area infested, damaged or dead
- 9: 81-90% of leaf area infested, damaged or dead
- 10: 91% of leaf area damaged to dead

While initial ratings on August 30 were made four days following the application of Transform, ratings are reflective of the visual presence of the initial leaf damage and honey-dew even though sugarcane aphid counts were affected. These ratings show considerable range of differences (0-8) in damage among all of the hybrids and within a type of hybrid. Ratings obtained two weeks following the insecticide application represented significantly less crop injury; ratings ranged from 0 to 30% (0 to 3) infested, damaged leaf area on September 10. Final ratings were 0 to 10% (0 to 1) infested, damaged leaf area on October 28. It is interesting to note that the hybrids did recover from the initial damage, as evident in the significantly reduced damage ratings from the September 5 to the October 28 sample dates. This recovery is likely due to additional plant growth following the insecticide application. Following the application of Transform, beneficial insect populations (including lady beetles) were very high. It is likely that both the Transform application and the beneficial insects mitigated further damage from the sugarcane aphids. It is not believed that 2015 sugarcane aphid infestation and damage was yield limiting due to the timely insecticide application.

**Acknowledgements:** We greatly appreciate Mr. Michael Menke for his cooperation, and Dr. Ed Bynum for his consultation on sugarcane aphids. Furthermore, we greatly appreciate the assistance Katrina Horn and Jonathan Moreno with seed preparation and planting, and Aislynn Walton, Jonathan Thobe and Travis Brown for field notes, harvest assistance and sample processing.

**Table 1. 2015 summary of key characteristics by sorghum type.** \*The number in parentheses represents the number of hybrids that make up each sorghum type. BMR= Brown midrib
