Introduction

The Cool-Season Annual Forage Variety Trial data presented in the following pages are the results from five trials coordinated and implemented by numerous Texas A&M AgriLife Extension and Research faculty and staff. We also appreciate the cooperation from Texas County Extension Agents, producers, and private industry partners that contributed locations, property, seed, time and other assets to conduct these field trials. The purpose of this publication is to provide unbiased yield data for forage producers across the state. With this information, Texas forage producers can make educated decisions regarding the most appropriate varieties for their geographic region.

Variety Selection:

Selection of an appropriate cool season forage variety is one of the most important decisions a producer will make. This decision can impact the potential yield (forage and/or grain), forage nutritive value, disease and insect management, and maturity of the crop. It is important that producers have diversity in the varieties planted on their farms to minimize production risks. The choice of varieties depends on the intended use of the crop (grain, forage, or dual-purpose). Variety diversification spreads the risk associated with potentially devastating pests (leaf and stripe rust, Hessian fly, wheat curl mite, greenbugs, etc.) and yield loss from adverse environmental factors (freeze, drought, hail, etc.).

Producers should select no fewer than two varieties to plant on their farms and preferably more, depending upon size, location, and purpose of fields. Variety selection should be based upon multiple years of sound data produced from university trials and other reliable sources. High yields over multiple years and multiple locations demonstrate a variety's ability to perform well over diverse environmental factors. Stable yield performance of quality grain or forage is the best variety selection tool. It is important to consider decreasing yield over a two or three year time frame, which may reflect a change in disease and/or insect resistance.

When selecting a variety for the 2014 season, producers should consider the variables that limited yield in the previous growing season; which may have had a negative impact on the results presented in the following pages. We strongly encourage producers to look at multiple year averages, where available, and to look at numerous relevant variety trial locations. Most locations in this publication will have multiple years of data presented.

Interpreting the Data:

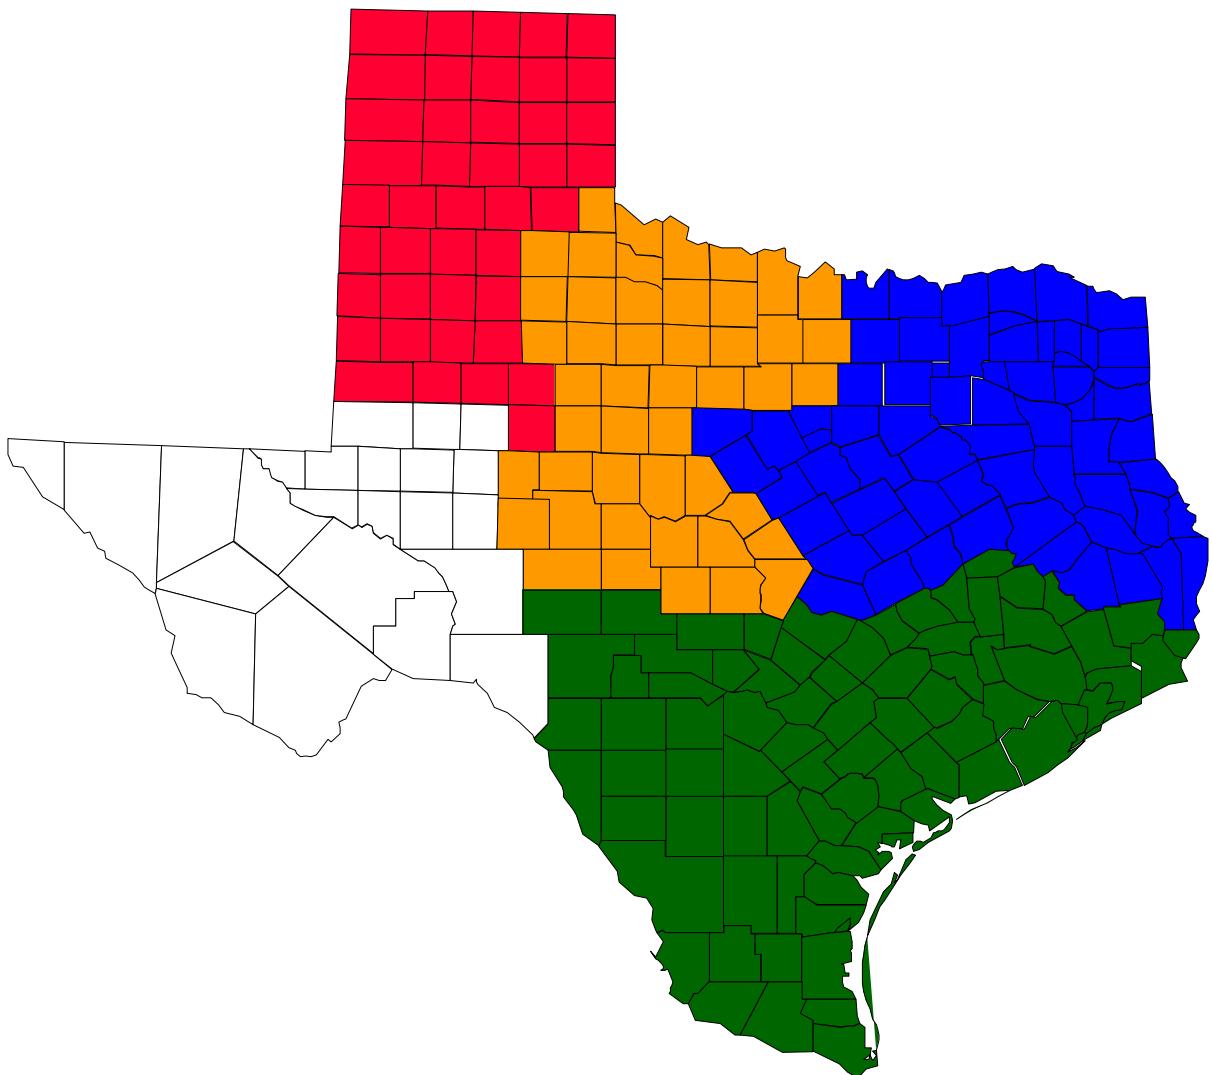

Forage yield, grain yield, and test weight at each location have been analyzed using appropriate statistical procedures. The statistical analysis provides the mean, CV, and LSD values. It is important to note these statistical values to prevent misinterpretation of any replicated data.

The mean is another term for the average. Therefore, a mean yield is the average of all the plots within a trial. Individual variety yields can be compared to the mean yield to determine how these varieties performed within the trial (i.e. were they above or below average?). This average can also be used as an indication of the environment for that location. A low mean yield can indicate poor growing conditions were experienced in that season; likewise, a high yield average can indicate favorable growing conditions.

The CV (Coefficient of Variation) value, expressed as a percentage, indicates the level of unexplained variability present within the trial. A high CV value indicates a lot of variability existed within the trial not related to normal variations that might be expected between the varieties in the test. This variability may be the result from non-uniform stands, non-uniform insect or disease pressure, variability in harvesting, or other issues. Generally, CV values in excess of 25% signify that there were problems in the trial, leading the reader to question the validity of the data as a true representation of varietal performance.

The LSD (Least Significant Difference) value is a numeric range to help the reader determine if the varieties performed differently from one another within the trial. If the LSD value is 2 ton/ac in a trial in which Variety A yielded 6 ton/ac and Variety B yielded 3 ton/ac, then Variety A is said to be significantly better. In that same trial with an LSD value of 2 ton/ac at a 0.05 (5%) significance level, the statistical inference one could say is that Variety A would yield better than Variety B in 19 out of 20 trials conducted in which there was at least a 2 ton/ac difference in yield. In this hypothetical comparison, you might have a 20th trial with a 2 ton/ac difference that there is not truly a difference between Variety A and B, but random chance caused the 2 ton difference.

| South Texas | |

2013 Texas Region Overview

Texas Blacklands:

The Texas Blacklands had an extremely good growing season for winter pasture compared to the rest of the state. Rainfall late in September allowed for many fields to be planted early for grazing. Unfortunately, if that rain was missed, the next significant rain event occurred late in December. Multiple freezing events in the spring may have hurt some producers in the area trying to harvest this crop for grain, but forage only producers didn't see any adverse effects. Insects had little affect in this year's forage crop. Late season rainfall came steady and often, causing delayed forage cuttings.

Texas High Plains:

Producers in the Texas High Plains struggled this winter with a continuing severe drought and numerous freezing events. Stand establishment was very difficult early in the season due to the drought when irrigation wasn't available. Dual-purpose crops were substantially injured by the March and April freezes. Insects and diseases were not a major problem in winter pastures in this area.

Texas Rolling Plains:

The Texas Rolling Plains producers also struggled while growing winter pastures. Dry conditions early in the season led to reduced stands and crop loss. Freezing events later in the season reduced the potential of grain yield significantly in crops grown also for seed production. Like the rest of the state, insects and diseases were not a major problem this year.

South Texas:

In the southern part of the state, conditions were not favorable to initiate winter pasture due to persistent drier conditions. If irrigation was not available, stands were reduced and even lost. Periods of lower temperatures were experienced in this part of the state as well; however, economic yield losses were not to the extent of the rest of the state. In some parts of South Texas, early dry conditions changed to late season storms with damaging winds and hail. Early season leaf rust was present and in some cases may have been a forage limiting factor. Insects were not a significant problem this season.

Forage Trial Agronomic Data

Location¹	Cooperator(s)	Yield Limiting Issues	Planting Date	Fertilizer (Total)	Pesticide Applied (Date)
				(lb N/a)	
College Station: Forage Only	Texas A&M Research and Extension Agronomy Farm	None	10/3/12	90	Huskie (10/30/12) Weedmaster (2/8/13)
College Station: Dual Purpose²	Texas A&M Research and Extension Agronomy Farm	Volunteer Corn Early	9/22/11	80	Finess G&B (10/11/11) Buctril (10/25/11) Dimethoate (2/22/12)
Comanche	Indian Creek Farm; Rodney Stephens	Dry Conditions Throughout	9/26/12	65	None
Delta County	Texas A&M Commerce Research Farm	Volunteer Wheat Early; Abandoned	9/28/12	None	None
McGregor: Dual Purpose	Texas A&M AgriLife Research and Extension Center	Some Barley Yellow Dwarf Virus	9/30/11	100	Dimethoate (2/27/12)
Millersview	Mickey Dillard Joe Beach Millersview Community Producers	Wildlife; Volunteer Small Grains	9/27/12	None	None
Vernon²	Texas A&M AgriLife Research and Extension Center —	Dry Conditions Throughout	9/27/12	45	None

¹These locations were planted with a seeding rate of 90 lb/a. All seed was treated with Gaucho XT at a rate of 3.4 oz/cwt.

²College Station, Comanche and Vernon were the only locations that irrigation was available. College Station required an additional 1.25 inches of supplemental irrigation, while Vernon only applied 0.5" for stand establishment.

¹Hard Red Winter Wheat (HRWW)

Soft Red Winter Wheat (SRWW)

Triticale (TRIT)

Winter Barley (WB)

Ryegrass entries were all Tetraploids

[†]Yield average for 2013 and 2012

[‡] Yield average for 2013, 2012, and 2011

^aTotal forage is the sum of all forage clippings

^bTrials with a coefficient of variation (CV) ≥ 25% contain excessive experimental error.

Readers should consider trials in a similar environment to confirm varietal yield.
