Introduction

The statewide Cool-Season Annual Forage Variety Trial data presented in the following pages are the results from five trials coordinated and implemented by Texas A&M AgriLife Extension and Research faculty and staff. We also appreciate the cooperation from County Extension Agents, producers, and private industry partners that contributed land property, seed, time, and other assets for the effective implementation of these trials. The purpose of this publication is to provide unbiased yield data for forage producers across the state. We hope that this information can assist Texas forage producers in identifying the most appropriate forage varieties for the growing conditions in their geographic regions.

Variety Selection:

The selection of an appropriate cool-season forage variety is one of the most important decisions a producer will make relative to their livestock operation. This decision can impact the potential forage yield, forage nutritive value, disease and insect management, and maturity of the crop, and thus, overall livestock performance. Producers need diversity in the varieties planted on their farms to minimize production risks. The choice of varieties depends on the intended use of the crop (forage only or dual-purpose) and when forage is most needed. Even though total forage production may be similar, certain species/varieties tend to produce more forage during the fall, winter, and/or spring. Variety diversification spreads the risk associated with potentially devastating pests (leaf and stripe rust, Hessian fly, wheat curl mite, greenbugs, etc.) and yield loss from adverse environmental factors (freeze, drought, etc.).

Producers should choose no fewer than two varieties to plant on their farms and preferably more, depending upon size, location, and purpose of fields. Variety selection should be based upon multiple years of sound data produced from university trials and other reliable sources. High yields over multiple years and multiple locations demonstrate a variety potential to perform well over diverse environments. Stable yield performance of forage is the best variety selection tool. It is important to consider decreasing yields over a two or three-year period, which may reflect a change in disease and/or insect resistance if weather conditions have remained similar.

When selecting a variety for the 2020-21 season, producers should consider the variables that limited yield in the previous growing season; which may have had a negative impact on the results presented in the following pages. We strongly encourage producers to look at multiple- year averages and to look at numerous relevant variety trial locations.

Interpreting the Data:

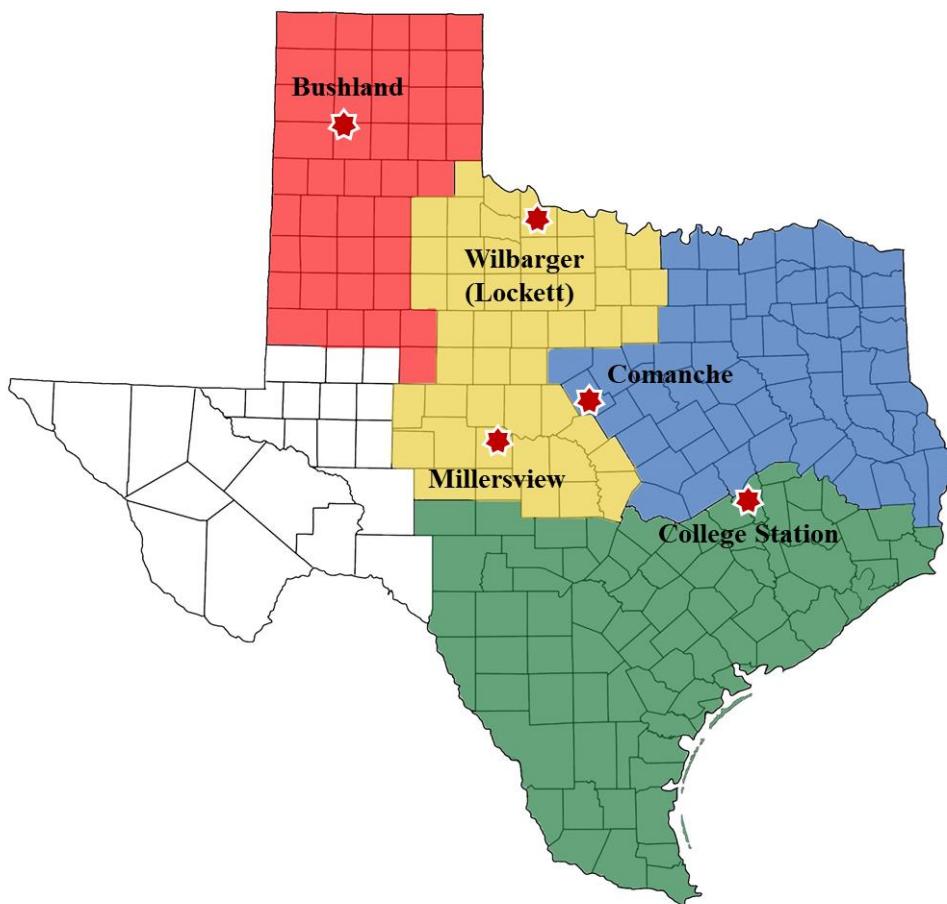

Forage yield at each location has been analyzed using appropriate statistical procedures. The statistical analysis provides the mean, CV, and LSD values. It is important to note these statistical values to prevent misinterpretation of any replicated data.

The mean is another term for the average. Therefore, a mean yield is the average of all the plots within a trial. Individual variety yields can be compared to the mean yield to determine how these varieties performed within the trial (i.e. were they above or below average?). This average can also be used as an indication of the environment for that location. A low mean yield can indicate poor growing conditions during the season; likewise, a high yield average can indicate favorable growing conditions.

The CV (Coefficient of Variation) value, expressed as a percentage, indicates the level of unexplained variability present within the trial. A high CV value indicates considerable variability existed within the trial not related to normal variations that might be expected among the varieties in the test. This variability may be the result of non-uniform stands, non-uniform insect or disease pressure, variability in harvesting, or other issues. Generally, CV values above 25% for forage trials signify that there were problems in the trial, leading the reader to question the validity of the data as a true representation of varietal performance.

The LSD (Least Significant Difference) value is a numeric range to help the reader determine if the varieties performed differently from one another within the trial. If the LSD value is 500 lb/ac in a trial in which Variety A yielded 6000 lb/ac and Variety B yielded 5000 lb/ac, then Variety A is said to be significantly better. In that same trial with an LSD value of 500 lb/ac at a 0.05 (5%) significance level, the statistical inference one could say is that Variety A would yield better than Variety B in 19 out of 20 trials conducted in which there was at least a 500 lb/ac difference in yield. In this hypothetical comparison, you might have a 20th trial with a 500 lb/ac difference that there is not truly a difference between Variety A and B, but random chance caused the 500 lb difference.

West Texas	

2020 Texas Region Overview

Texas High Plains: Variable rainfall in August and September 2020 resulted in varying planting conditions across the Texas High Plains. Some fields were planted with replenished soil moisture while other fields were sown under dry conditions. October 2019 rains delivered valuable moisture for the region's crops. There was minimal winter precipitation in 2019 through the central and northern Panhandle resulting in another dry winter. Dryland fields benefited from March 2020 rain. April 2020 freezes resulted in varying degrees of injury to the crops. Conditions rapidly changed in late April 2020. Above-average temperatures through May 2020 drove the forage-crop water demand, resulting in water stress. Because of warm, dry conditions, disease pressure was minimal during late spring of 2020.

Texas Rolling Plains: The season started with hot and dry conditions in the fall of 2019. Soil temperature was not optimum for planting forages until the first week of October 2019. Dry months continued to the end of December 2019, which reduced winter forage productivity throughout the Texas Rolling Plains. The performance of forage crops improved with the precipitations observed during the January – March 2020 period.

Texas Blacklands: The 2019/2020 growing season was characterized by prolonged rains from the start, and, in many instances, the excessive rain delayed planting. The occurrence of a cold front in March 2020 brought below-freezing temperatures that caused some freeze damage to cold-sensitive varieties in some fields. Wet conditions continued in May and June 2020 delaying harvest in some fields.

South Texas. Very hot and dry conditions characterized the beginning of the 2019/2020 growing season, followed by cold weather and rain in late October 2019, which allowed timely plantings for most of the locations. Intense and prolonged rains observed during much of the early growing season affected the performance of forage crops. Disease pressure was not as high as what was observed in previous seasons, although the occurrence of leaf rust, and to a minor extent of stripe rust, caused yield damage in some fields.

Forage Trial Agronomic Data

Location¹	Cooperator(s)	Yield Limiting Issues	Planting Date	Fertilizer Total (lb N/A)	Pesticide Applied (Date)
Bushland²	Texas A&M AgriLife Research and Extension Center	Heavy rain after planting, severe drought thereafter	09/23/19	40	Quelex (3/11/20)
College Station	Texas A&M Research and Extension Agronomy Farm	Wet season	10/07/19	50	Ally/Amber (12/13/19)
Comanche²	Indian Creek Farm; Rodney Stephens	None	11/5/19	111	None
Wilbarger (Lockett)	Texas A&M AgriLife Research and Extension Center	None	10/01/18	138	None
Millersview	Mickey Dillard	None	10/28/19	35	None

¹These locations were planted with a seeding rate of 1.2 million seed/ac except for ryegrass which was 25 lb/ac. All seed was treated with Cruiser Maxx Vibrance for Cereals.

²Bushland and Comanche were the only locations where irrigation was available.
